NMR Data, Ultrahigh Resolution

Ultrahigh resolution  $^{15}\text{N}$  NMR spectra were measured for two nitroalkanes ( $\text{MeNO}_2$  **1a**,  $^t\text{BuNO}_2$  **1c**), two isocyanates ( $^t\text{BuNCO}$  **2c**,  $\text{Me}_3\text{SiNCO}$  **2d**), four isothiocyanates ( $\text{MeNCS}$  **3a**,  $\text{EtNCS}$  **3b**,  $^t\text{BuNCS}$  **3c**,  $\text{Me}_3\text{SiNCS}$  **3d**), one carbodiimide ( $\text{Me}_3\text{SiNCNSiMe}_3$  **4d**), one keteneimine [ $\text{Me}_3\text{SiNCC}(\text{SiMe}_3)_2$  **5d**], two sulphanyl imides ( $^t\text{BuNSO}$  **6c**,  $\text{Me}_3\text{SiNSO}$  **6d**), and *N-tert*-butyl-pyrrole **7c**, in order to determine coupling constants  $J(^{15}\text{N}, ^{13}\text{C})$  and isotope induced chemical shifts  $^1\Delta^{12/13}\text{C}(^{15}\text{N})$  at the natural abundance of the isotopes. The values  $^1\Delta^{12/13}\text{C}(^{15}\text{N})$  can be separated into two groups, one dealing with NC single and another one with NC double bonds. In each group (with few exceptions), the values  $^1\Delta^{12/13}\text{C}(^{15}\text{N})$  become more negative with a decrease in the absolute magnitude of  $|J(^{15}\text{N}, ^{13}\text{C})|$ . The corresponding values  $^1\Delta^{14/15}\text{N}(^{13}\text{C})$  show a similar behaviour. However, *N*-substituted pyrroles appear to be exceptional in this respect.
