*Pueraria candollei* Wall. ex Benth. var. *mirifica* (Airy Shaw & Suvat.) Niyomdham was investigated for callus induction using Murashige and Skoog (MS) medium containing different plant growth regulators. After 8 weeks of culture, 66–100% of leaf or stem explants formed calli. Calli from stem explants cultured on MS medium supplemented with 0.5 mg/l thidiazuron (TDZ) gave the maximum of shoot induction (16%) and the highest level of total isoflavonoids \[(50.39 \pm 7.06) \text{ mg/g dry wt}\], which was 7-fold higher than that of the native tuber \[(7.04 \pm 0.29) \text{ mg/g dry wt}\]. These results suggest that addition of TDZ to the culture medium markedly enhances the production of isoflavonoids in calli induced from stem explants of *P. candollei* var. *mirifica*.
